Abstract

We compiled a list of the known maxima of vascular plant species richness in the steppe zone of Ukraine at different sampling scales ($0.0001\text{--}100\text{ m}^2$) and compared them with the world records. Detailed information on each of the identified species-rich grassland plots is provided, including site descriptions, plot characteristics, coordinates, and species lists. Most of the small-scale records (up to 0.1 m^2) were found in mesic grasslands in southern Ukraine (Kherson region) with a high abundance of annual grasses and forbs: 9 and 11 vascular plant species in 0.0001 m^2 and 0.001 m^2 , respectively, in the steppe depression Chorna Dolyna, and 26 species in 0.1 m^2 in a mesic psammophytic grassland in the Dzharylhach National Nature Park. Most of the records at larger scales were made in the northern part of the steppe zone, in forb-rich and forb-grass steppes: 15, 39, 73, and 107 species in $0.01\text{, }1\text{, }10\text{, and }100\text{ m}^2$, respectively. All richness records were characterised by neutral to slightly alkaline substrates (soil pH 7.0–7.7) and low-intensity management. These characteristics are consistent with the known patterns from world records of species richness. Our inventory provides baseline knowledge for studies on the high species richness in the steppe zone and can stimulate the further investigation of identified species-rich grasslands, as well as the search for new ones. Since we did not specifically search for species-rich sites, and our dataset includes only a relatively small number of plots compared to similar studies in other regions, we expect that more species-rich vegetation will be found with further research. This study highlights the importance of steppe grasslands as global biodiversity hotspots and draws attention to their protection in the context of land-use changes and the consequences of the war in Ukraine.

Keywords: alpha diversity, biodiversity, grassland, maximum, spatial scale, species richness, steppe, Ukraine, vascular plant, vegetation plot.

Erweiterte deutsche Zusammenfassung am Ende des Artikels

1. Introduction

Temperate grasslands in Europe are known for their high species diversity, including most of the known world records for grain sizes below 100 m^2 (Zobel 1992, Wilson et al. 2012, Chytrý et al. 2015). Studies of maximum species richness provide valuable insights into the diversity, distribution, and conservation of grassland ecosystems, as well as into the ecological theory of fine-scale species coexistence and the maintenance of high species diversity (Chytrý et al. 2015, Biurrun et al. 2021). Factors such as soil properties, climate, and land-use practices are thought to play a crucial role in shaping the richness records (Roleček et al. 2014, Palpurina et al. 2015).

Almost all of the known species richness maxima represent meso-xeric and mesic grassland communities in Central Europe, such as the grasslands of the White Carpathians in the Czech Republic and Slovakia (Chytrý et al. 2015), Romanian Transylvania (Dengler et al. 2012, Turtureanu et al. 2014, Roleček et al. 2021), and western Ukraine (Roleček et al. 2014). These regions represent the westernmost part of the forest-steppe in Europe and its transition to the nemoral zone. These regions have been studied for a long time by many experienced botanists, which can increase the probability of finding new records (Chytrý et al. 2015, Hájek et al. 2020). Species richness values close to these maxima described above were also reported from Estonia (Kull & Zobel 1991, Sammul et al. 2003), Sweden, and northern Germany, where intensive vegetation sampling has been carried out and a large number of high-quality plots are available.

There are only a few reports of outstanding plant species richness from the steppe biome in Eastern Europe, most of them stemming from the forest-steppe regions with meadow-steppe vegetation. For example, 77, 87, and 88 species in 1 m^2 and 110 and 130 species in

100 m² were reported from the central chernozem steppe in the Kursk region (van der Maarel & Titlyanova 1989, Vasilevich 2009), but without species composition data or precise coordinates. The world's richness record of 119 species at 16 m² was recorded in the meadow steppes near the Spaska village in Chernivtsi region, Ukraine (Roleček et al. 2019). Well-documented richness records at different grain sizes from the Eurasian steppe biome have been reported from the EDGG Field Workshops in the forest-steppe zone in Central Podolia, Ukraine (Kuzemko et al. 2016), and in the transition between the forest-steppe and steppe zones in Khakassia, Siberia (Polyakova et al. 2016). However, most of the steppe biome is not yet covered by systematic vegetation sampling, which significantly complicates the search for and documentation of species richness records.

To help fill this knowledge gap, we compiled hitherto scattered or unpublished data on plant species richness in the steppe zone of Ukraine at different scales. Specifically, we aimed to reveal where and under which conditions particular species-rich grasslands occur and how their diversity compares to the known records from other regions.

2. Methods

In our study, we searched for species-rich plots of grassland vegetation in the steppe zone of Ukraine. We collected all available data on the vascular species richness of grassland habitats, including data from vegetation databases, literature, and our own fieldwork. We limited the selection of relevés to those with coordinates, a specified plot size, and species composition data (list of vascular plant species recorded). We considered data from all grassland habitats that occur in the steppe zone (Kuzemko et al. 2022). The resulting dataset contained 7781 plots (Fig. 1), including 4309 plots that were sampled by our team in 2005–2023, mainly in the western part of the steppe zone in Ukraine (Kherson, Mykolaiv, and Odesa regions). All of these plots were delimited with a tape measure. To obtain nested series data, we used the standard EDGG methodology (Dengler et al. 2016, 2021) with seven grain sizes ranging between 0.0001 and 100 m² nested within each other, thus resulting in a total of 183 nested plot series with species richness data at seven different scales. The species occurrences within each plot of the nested series were assessed by shoot presence. A further 3472 vegetation plots (size range: 0.5–100 m²; sampled in 1953–2020) were obtained from the following three phytosociological databases: the Eastern European Steppe Database (EU-00-030; Vynokurov et al. 2020), the Ukrainian Grassland Database (EU-UA-001; Kuzemko 2012), and the Vegetation Database of Ukraine and Adjacent Parts of Russia (EU-UA-006). The method and accuracy of measurement was unknown for most of the data from these databases. In addition to the vegetation plots from sources which were already included in the databases, we also searched for relevant data published in PhD theses which focus on the vegetation of the steppe zone in Ukraine, as well as articles in the archives of the Ukrainian Botanical Journal (<https://ukrbotj.co.ua/archive>), Chornomorski Botanical Journal (<https://cbj.kspu.edu/index.php/en/main>), and in Google Scholar using the following search string in English: ‘species richness’ & (‘grassland’ / ‘steppe’ / ‘steppe zone’) & ‘Ukraine’; and in the Ukrainian language: (‘видове багатство’ / ‘видова насыщеність’) & (‘лукі’ / ‘степи’ / ‘степова зона’) & ‘Україна’.

Species richness (number of species) was counted for vascular plants only. Records of the same species in different layers (e.g. seedling, juvenile, shrub) were merged. The nomenclature of vascular plants followed the Ukrainian checklist (Mosyakin & Fedorochuk 1999). For the plots with maximum richness records, we also checked whether the number of species differed when following the Euro+Med nomenclature (Euro+Med PlantBase; <http://ww2.bgbm.org/EuroPlusMed/>, accessed 2023-10-15).

For the inventory and documentation of the record plots, we followed the approach by Chytrý et al. (2015). For each of the identified species-rich grassland plots, we provided the following information: site descriptions, plot characteristics, coordinates, and species lists. This way of presenting information about the plots allows for future verification and clarification of the plots, and also facilitates further analysis and the comparison of species richness records in different regions.

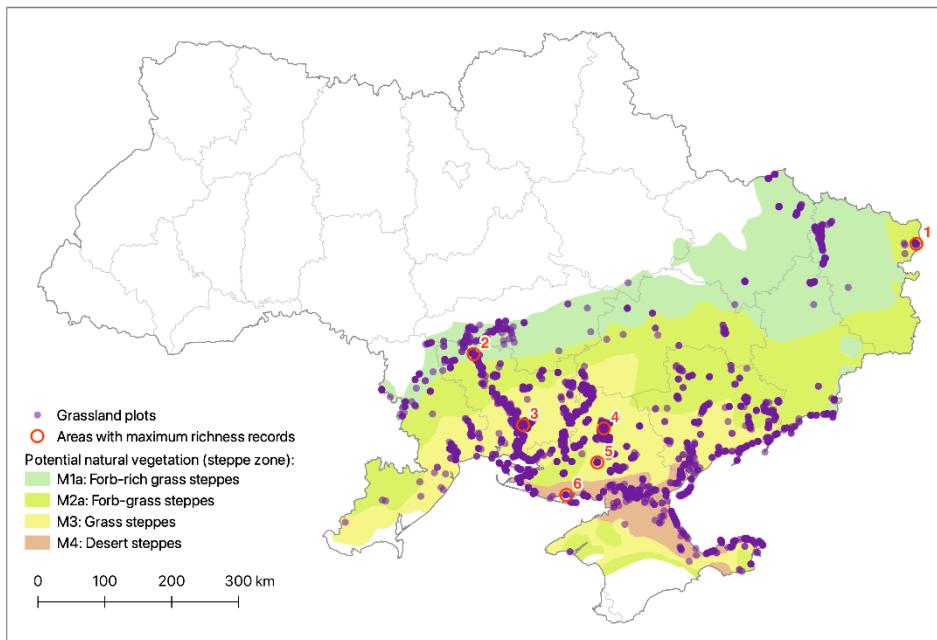

Fig. 1. Locations of analysed grassland plots (dots) and potential natural vegetation for the steppe zone in Ukraine according to Bohn et al. (2000) (background colours). Locations with a high density of sampled plots are indicated by darker points. Areas 1–6 and their richness records are described in the Results.

Abb. 1. Orte der untersuchten Grasländer (Punkte) und potenzielle natürliche Vegetation der Steppenzone der Ukraine nach Bohn et al. (2000) (Hintergrundfarben). Standorte mit einer hohen Dichte an Probeflächen sind durch dunklere Punkte gekennzeichnet. Die Gebiete 1–6 mit Rekorden des Artenreichtums sind im Ergebnisseite beschrieben.

To compare our results to the world richness records, we compiled an updated list of the published world records of species richness in grasslands based on the following literature sources: for the 0.0001 m^2 grain size – 11 species (Biurrun et al. 2021), 0.001 m^2 – 19 species (meso-xeric grassland in Spain; mentioned in Dengler et al. 2016, 2020), 0.01 m^2 – 25 species (wooded meadow in Estonia, Kull & Zobel 1991), 0.1 m^2 – 47 species (meso-xeric grassland in Switzerland; 47 species for 0.09 m^2 published in Riedel et al. 2023), 1 m^2 – 89 species (mountain grassland in Argentina, Cantero et al. 1999), 10 m^2 – 115 species (Romania, Roleček et al. 2021), and 100 m^2 – 133 species (Czech Republic, Chytrý et al. 2015). All the listed world records of species richness are from grasslands located in Europe, except for the 1-m^2 record of 89 species from Argentinian grasslands. For Europe, the maximum species richness on 1 m^2 is 82 species, as reported in the White Carpathians by Hájek et al. (2020).

We also considered the distribution of richness records in the four different steppe subzones, using the map of the potential natural vegetation of Europe (Bohn et al. 2000): forb-rich (originally referred to as “herb-rich” in Bohn et al. 2000) grass steppes (M1a), forb-grass (originally referred to as “herb-grass”) steppes (M2a), grass steppes (M3), and desert steppes (M4) (Fig. 1).

3. Results

The highest species richness values in the steppe zone of Ukraine and its subzones are shown in Figure 2, Table 1, and Supplement E1. Most of the plots in the dataset were represented by the following seven grain sizes: 0.0001, 0.001, 0.01, 0.1, 1, 10, and 100 m². In Figure 2, the maximum richness values for each of these plot sizes in Ukraine are compared with the known world richness records. Since plots with a size other than the standard ones listed above had lower maximum richness values than their nearest neighbour standard plots, e.g. plots of 16 and 25 m² had lower richness maxima than standard 10-m² plots, we do not list these plots in this paper.

Mean richness values (Table 1) differed only slightly between the different steppe subzones at the smallest scales (up to 0.1 m²). At the largest scales (from 1 to 100 m²), a strong trend of decreasing species richness was observed between the highest values in northern forb-rich steppes (M1a) and the lowest values in the southern desert steppes (M4). The calculated means could be affected by unequal representation of different habitat types in different subzones or by unequal sampling effort.

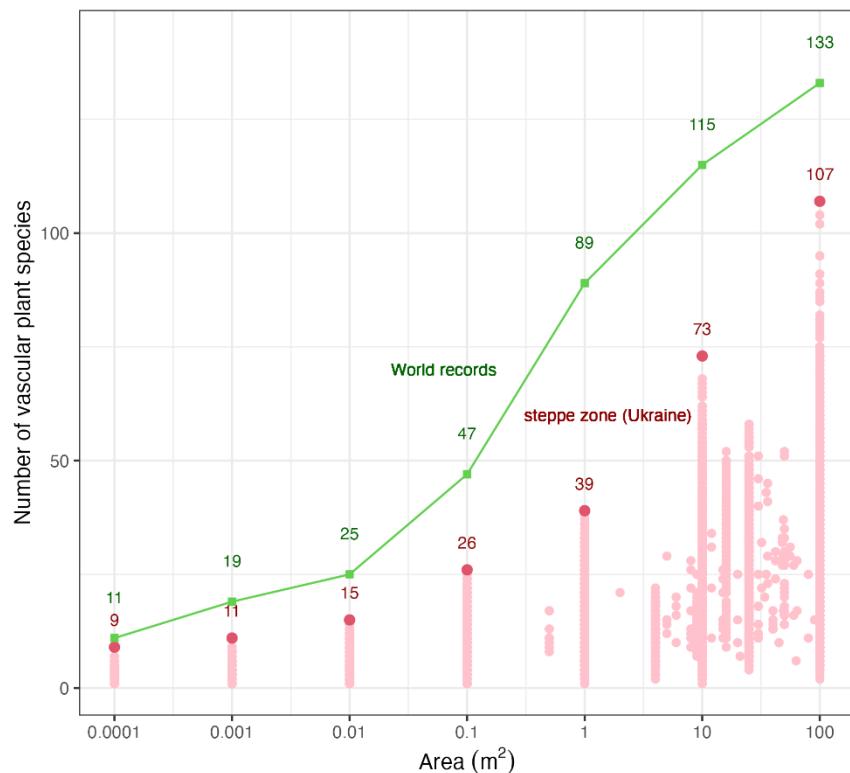

Fig. 2. Counts of vascular plant species recorded in grassland vegetation plots of different size from the steppe zone in Ukraine (in red) compared with the known world records for grasslands (in green). Maximum counts for Ukrainian steppes and world records are shown as numbers.

							68 20.4 444

3.1 Comparison of maximum richness values with the known records

The species richness record at the smallest scale, 9 vascular plant species on 0.0001 m², is similar to the published world record. Including bryophyte species, the Ukrainian record coincides with the published world record of 11 species (Moysiyenko et al. 2022). The maximum difference was observed at 1 m²: 89 species in the world record vs. 39 species in the steppe zone in Ukraine (-56%), and at 0.001 m²: 11 species vs. 19 species (-42%). At 10 m², the difference was also quite large: 115 species compared to 73 species (-37%). At 100 m², the record from Ukrainian steppe zone (107 species) was closer (-20%) to the previously published world record in grasslands (133 species) than the records at 1 and 10 m².

Compared to the maximum richness counts from the transition between forest-steppe and steppe zone in Khakassia (Polyakova et al. 2016), our records of species richness were higher at the scales of 0.0001 m² (9 species in steppe Ukraine vs. 5 species in Khakassia), 0.001 m² (11 vs. 9 species), 10 m² (73 vs. 72 species), and 100 m² (104 vs. 94 species). However, the records at the following intermediate scales were lower in Ukraine: 0.01 m² (15 vs. 18 species), 0.1 m² (26 vs. 28 species) and 1 m² (39 vs. 52 species).

3.2 Description of the sites with species richness records

Most of the records at larger scales (1–100 m²) were recorded in the northern part of the steppe zone. The “Striltsivskyi steppe” compartment of the Luhansk Nature Reserve in Eastern Ukraine, Luhansk Region (Fig. 1, area 1; Fig. 3a, b), is known for its rich forb-bunchgrass steppe dominated by *Festuca rupicola*, *Stipa tirsia*, *S. zalesskii* and forbs such as *Aster amellus*, *Filipendula vulgaris*, *Fragaria viridis*, and *Salvia nutans*. The most species-rich plots were sampled by Larysa Borovyk for her dissertation in the 2000s (Supplement E1: records 36 and 41), including the richness record for the steppe zone – 107 species in 100 m² (Fig. 3a). The most species-rich plot represented forb-rich steppe with

low steppe shrubs, such as *Amygdalus nana*, *Caragana frutex*, and *Chamaecytisus ruthenicus*. However, plots smaller than 100 m² were not sampled in this area. According to the latest available data from the Luhansk Nature Reserve (fieldwork by L. Borovyk in 2021), the grasslands are gradually degrading due to the absence of necessary management, causing the spread of invasive and expansive species. Currently, further field studies in the reserve are not possible due to the war.

Forb-rich meso-xeric steppes in the northern part of the steppe zone in the Dnipro Uplands (Mykolaiv and Kirovohrad regions) account for most of the records at larger scales. The natural vegetation of the region is characterised by a patchwork of dry grasslands, steppic shrubs, rocky outcrops, and thermophilous forests. During our fieldwork in the Buzkyi Gard National Nature Park in the Mykolaiv region (Fig. 1, area 2; Fig. 3c, d), we found most of the species richness maxima at the larger scales. In particular, several records were sampled in 2021 during a survey of newly established monitoring plots: 104, 102, and 94 species in 100 m²; 73 and 68 species in 10 m²; 39 species in 1 m²; 24 and 23 species in 0.1 m²; and 15 species in 0.01 m² (Supplement E1: records 7, 20, 25, 27, 32, 37, 38, and 39). The results were recorded in forb-rich grasslands with initial stages of shrub encroachment and low-intensity grazing. During the last years before sampling, the grazing intensity in this area had gradually decreased. The dominant species among the grasses were *Festuca rupicola*, *Stipa dasypylla*, and *Koeleria macrantha*; and among the forbs *Ferulago galbanifera*, *Fragaria viridis*, *Jurinea arachnoidea*, *Potentilla incana*, *Salvia nutans*, *Teucrium polium*, etc. Woody species were represented by steppe shrubs, saplings, and seedlings: *Caragana mollis*, *Chamaecytisus austriacus*, *Crataegus monogyna*, *Pyrus communis*, *Rhamnus cathartica*, and others. The presence of *Alyssum murale*, *Scleranthus annuus*, and *Sempervivum ruthenicum* indicated nearby rock outcrops. The pH of the soil ranged from neutral to slightly alkaline (7.0–7.4).

The lower reaches of the Dnipro, Southern Buh, and Ingul rivers are characterised by numerous steppe ravines with complex topography and outcrops of Sarmatian limestone. Species-rich grasslands were found in extra-zonal meso-xeric forb-grass steppes and zonal grass steppes. In the Kamianska Sich National Nature Park in the Kherson Region (Fig. 1, area 4; Fig. 3e, f), we sampled plots with 38 species in 1 m², 59 species in 10 m², and 95 and 87 species in 100 m² (Supplement E1: records 28, 34, 40, and 42). In the lower reaches of the Southern Buh and Inhl Rivers (Fig. 1, area 3; Fig. 4a, b), we recorded 25 species in 0.1 m², 39 species in 1 m² (Supplement E1: records 18 and 26), and 65 species in 10 m² (Supplement E1: record 33). The surveyed sites with high species richness were located on gentle slopes with NE and NW exposure, in some cases on shallow soils with limestone outcrops covered by closed grassland vegetation. The vegetation was rich in both grasses (*Bromopsis riparia*, *Koeleria macrantha*, *Stipa lessingiana*) and forbs (*Euphorbia stepposa*, *Inula oculus-christi*, *Nepeta parviflora*, *Phlomis pungens*, *Salvia nemorosa*, *Teucrium polium*). The land use in most cases was low-intensity grazing.

Mesic steppe depressions and mesic psammophytic grasslands in Southern Ukraine (Kherson Region: Fig. 1, areas 5 and 6) hosted most of the small-scale maxima. In the steppe depression “Chorna Dolyna” (Fig. 1, area 5; Fig. 4c, d), we sampled 9 species in 0.0001 m² and 11 species in 0.001 m² (Supplement E1: records 1 and 3). The site is a mesic grassland on slightly alkaline soil (pH = 7.7), grazed and mown once a year. The vegetation is dominated by the annual grass *Ventenata dubia* and rich in annual forbs such as *Anthemis ruthenica*, *Cerastium glutinosum*, *Erophila verna*, *Lotus angustissimus*, and *Scleranthus verticillatus*. Perennial graminoids are also abundant, including *Carex melanostachya*,

Elytrigia pseudocaesia, and *Poa angustifolia*. This particular vegetation represents grasslands unique to the steppe zone known as steppe depressions or ‘pody’ (Shapoval & Kuzemko 2021). In a grazed mesic psammophytic grassland on neutral soil (soil pH = 7.1) near Skadovsk in the Dzharylhach National Nature Park (Fig. 1, area 6; Fig. 4e, f), we recorded 26 species in 0.1 m² (Supplement E1: record 17). The vegetation of this species-rich mesic site is also remarkable for the large number of annuals.

4. Discussion

Species-rich grasslands in the steppe zone in Ukraine resemble patterns previously evidenced from the other regions. Almost all of the known species richness records and near-maximum richness values for scales below 100 m² were found in meso-xeric grassland communities across Europe (Chytrý et al. 2015, Dengler et al. 2020, Hájek et al. 2020, Riedel et al. 2023). All identified records from the steppe zone represent meso-xeric and, at small scales, mesic grasslands. At the smallest scales (up to 0.1 m²), our records were found in a specific type of mesic grassland with a large number of annuals. The small size of annual plants may allow them to occupy tiny niches within the plots, increasing the species richness found at these grain sizes. However, these plots were recorded as shoot presence, so overlap between plants in different sub-layers also could play a role. For example, low-growing annuals could overlap with the stems of perennials above.

The initial stages of forest and shrub encroachment create favourable conditions for increasing small-scale heterogeneity. This is known from Estonian wooded meadows (Kull & Zobel 1991) and confirmed in the case of grasslands with shrub encroachment in the steppe zone of Buzkyi Gard and Kamianska Sich National Nature Parks in Ukraine. Landscape diversity and the historical persistence of landscapes and land use are known factors that positively influence species richness (Pärtel et al. 1999, Gazol et al. 2012). The landscapes that surround the grasslands in both Buzkyi Gard and Kamianska Sich National Nature Parks represent a mosaic of dry grasslands, steppic shrubs, rocky outcrops, and, in the case of Buzky Gard, thermophilous forests. Such landscape heterogeneity could increase the regional species pool. In general, most of our records we found in protected areas which are large complexes of natural landscapes, usually with a long history of continuous and stable land-use conditions.

Some of the known world records come from regions that have been intensively studied over long time periods by experienced teams of botanists. The identification of the most species-rich plots below 1 m² is not always associated with a specific area’s size, and is strongly limited by the availability of data from certain regions, such as data from long-term monitoring experiments that have accumulated thousands of plots over decades (Chytrý et al. 2015) or intensive fine-scale sampling in regions with diverse and species-rich vegetation (Dengler et al. 2012). It should be noted that revisiting previously known species-rich sites may reveal an even higher species richness than previously recorded. This occurred with the known richness records at larger scales (10–100 m²) in the White Carpathians and Romania (Chytrý et al. 2015, Hájek et al. 2020, Roleček et al. 2021).

Until recently, vegetation sampling in the Ukrainian steppe zone was mostly episodic, lacking targeted searches for species-rich plots and in many cases without the use of accurate measurement methods. In addition, the dominant approach to vegetation classification traditionally used in Ukraine during the 20th century did not require a very precise sampling procedure. Most of the species richness maxima in the analysed dataset were recorded

during the last 15 years, using the standard EDGG methodology with seven grain sizes between 0.0001 and 100 m² (Dengler et al. 2016, 2021). Other regional maxima for 100 m² have also recently been recorded during sampling of fixed monitoring plots in protected areas. Thus, we assume that the accumulation of information on species richness records in the Ukrainian steppe zone has only just begun.

The ongoing war as a result of the Russian invasion of the southern and eastern regions of Ukraine has severely limited current and future opportunities for conducting further vegetation research. Almost the entire steppe zone is affected by this military action. Except for the right bank of the Dnipro, the steppe zone is either within the front line or temporarily occupied. This increases the risk of destruction or possible extinction for certain vegetation types and plant species, including the small-scale richness hotspots in steppe depressions and meso-xeric species-rich grasslands in the Kherson region that have been surveyed (Skobel et al. 2023).

In addition, the war has exacerbated existing problems with grassland management in Ukraine, particularly in nature conservation areas. Most records were found in areas of low management intensity, highlighting the importance of moderate disturbance in maintaining species-rich grasslands. A few records from the Luhansk Nature Reserve and the Buzkyi Gard National Nature Park were found in the areas that had previously been intensively grazed, but where grazing had gradually decreased over the last decade prior to sampling. Therefore, at the time of fieldwork, these areas were in the process of successional change. However, further continuation of this succession may lead to the complete overgrowth of grasslands with shrubs. This problem is linked to the rapid decrease of traditional pasture and hay meadow use since the 1990s due to the decline of rural areas and traditional farming. At the same time, nature conservation areas in Ukraine do not have the legal and financial means to organise subsidies for grassland management. Since most of the grasslands in Ukraine are small fragments in the transformed agricultural landscape and do not represent a complete steppe ecosystem (e.g. including steppe animals), their long-term existence remains questionable without appropriate management. Appropriate management is particularly critical for grasslands in the northern part of the steppe zone, since they produce more biomass and are more sensitive to shrub encroachment.

5. Conclusions

The steppe zone is characterised by a continental dry climate which creates harsher environmental conditions for the vegetation compared to the forest-steppe zone. Our data suggest that local topography, landscape heterogeneity, and low-intensity management provide the basis for the existence of species-rich grasslands in the steppe zone. We hope that our contemporary overview will stimulate further studies investigating these biodiversity hotspots and identifying new ones. Since 2022, military action in southern Ukraine has limited current and future opportunities for conducting additional research and conservation and management activities in the steppe zone. Documentation of the pre-war biodiversity (see also Skobel et al. 2023) is therefore an important task, since it provides a basis for future estimates of biodiversity change and restoration.

Erweiterte deutsche Zusammenfassung

Einleitung – Das Verständnis der Muster von außergewöhnlichem Artenreichtum ist wichtig für die Kenntnis von Ökosystemen und deren Erhaltung (Chytrý et al. 2015, Biurrun et al. 2021). Existierende Berichte über einen hohen Artenreichtum auf Flächen von weniger als 100 m² stammen hauptsächlich von gemäßigten meso-xerischen und mesischen Grasländern in Mitteleuropa (Zobel 1992, Wilson et al. 2012, Chytrý et al. 2015), die nach dem europäischen Naturschutzrecht zu den prioritären Lebensraumtypen gehören. Es gibt nur wenige Berichte über herausragenden Pflanzenartenreichtum aus dem Steppenbiom Osteuropas, die meisten davon stammen aus Wiesensteppenvegetation in den Waldsteppengebieten. Um einen Beitrag zur Schließung dieser Wissenslücke zu leisten, haben wir die bisher verstreuten oder unveröffentlichten Daten zum Pflanzenartenreichtum der Steppenzone der Ukraine auf verschiedenen räumlichen Skalen zusammengetragen.

Methoden – Wir sammelten alle verfügbaren Daten zum Gefäßpflanzenartenreichtum von Graslandlebensräumen, einschließlich eigener Daten, aus Vegetationsdatenbanken und der Literatur. Wir analysierten 6826 Vegetationsaufnahmen unterschiedlicher Größe, um den Artenreichtum auf verschiedenen Skalen zu untersuchen und verglichen diese Ergebnisse mit bekannten globalen Maxima. Wir untersuchten auch die Verteilung der Artenreichtumsrekorde in den vier Teilzonen der Steppenzone, basierend auf der Karte der potentiellen natürlichen Vegetation Europas (Bohn et al. 2000).

Ergebnisse – Die meisten kleinfächigen Nachweise (bis 0,1 m²) wurden in mesischen Graslandgesellschaften mit einem hohen Anteil an einjährigen Gräsern und Kräutern in der südlichen Ukraine (Region Kherson) gefunden: 9 bzw. 11 Gefäßpflanzenarten auf 0,0001 m² bzw. 0,001 m² in der Steppensenke Chorna Dolyyna bzw. 26 Arten auf 0,1 m² in einem mesischen psammophytischen Grasland im Nationalen Naturpark Dzharylhach. Bei der kleinsten Flächengröße (0,0001 m²) lag unser Ergebnis nahe am Weltrekord (9 vs. 11 Arten). Die meisten Maxima auf größeren Flächen wurden im nördlichen Teil der Steppenzone, in den krautreichen Steppen, gefunden: 15, 39, 73 und 107 Arten auf 0,01, 1, 10 bzw. 100 m². Alle Rekorde des Artenreichtums waren durch neutrale bis leicht alkalische Substrate (Boden-pH 7,0–7,7) und eine wenig intensive Bewirtschaftung gekennzeichnet.

Diskussion – Wir diskutieren, dass Faktoren wie Landschaftsheterogenität und extensive Bewirtschaftung zum Artenreichtum des Graslands beitragen. Der anhaltende militärische Konflikt in der Ukraine schränkt hier jedoch aktuelle und zukünftige Forschungsmöglichkeiten in der Steppenzone ein. Umso wichtiger ist, dass die Biodiversität von vor dem Krieg dokumentiert wird, um später ihre Veränderungen bewerten und sie in Zukunft wiederherstellen zu können.

Acknowledgements

We thank the Eurasian Dry Grassland Group (EDGG) and the National Research Foundation of Ukraine (Project No. 2020.01/0140) for supporting fieldwork in the steppe zone, in particular for organizing the workshop “Grasslands and coastal habitats of Southern Ukraine” in 2021, and Rufford Small Grant (ID 27637-1) for supporting fieldwork in the Buzkyi Gard National Nature Park. The work of Daria Borovyk was supported by the Visegrad Fund Scholarship (ID 52010644) and the IAVS Early Career Supporting Grant (2023). We are very grateful to Thomas Becker and the anonymous reviewer for their review and helpful comments and to Hallie Seiler for the linguistic editing. We also acknowledge the sCaleGrassDiv project, supported by the sDiv, the Synthesis Centre of iDiv, for the work on the grassland datasets from Ukraine and discussions about diversity records. Special thanks to the administrations of the Azov-Syvash National Nature Park, Black Sea Biosphere Reserve, Biloberezhzhia Sviatoslava National Nature Park, Buzkyi Gard National Nature Park, Kamianska Sich National Nature Park, and Oleshkivski Pisky National Nature Park for providing permits and assistance during the fieldwork. We also thank Galyna Gouz for providing her photo from the Luhansk Nature Reserve. Last but not least, we are exceedingly grateful to the Armed Forces of Ukraine and all Ukrainians for their courage and resistance against the Russian aggression in Ukraine.

Author contributions

DB conceived the idea, performed data collection and analyses, and led the writing. ID, JD, RG, AK, KL, IM, NS, and DV revised the initial version of the manuscript. All authors contributed data and checked the final version of the manuscript.

Supplement E1. Data of extraordinarily species-rich plots in the steppe zone in Ukraine.

Anhang E1. Daten der außerordentlich artenreichen Vegetationsaufnahmen in der Ukraine.

Vegetation plots with richness records sampled in the steppe zone in Ukraine. Plots with maximum richness for all grain sizes (0.0001–100 m²) and other plots with a similar number of species (close to maximum) are given. In cases where several plots with a similar number of species at the same sampling scale were located close together (closely located monitoring plots, plots in different corners of the same nested plot series), only one plot with the maximum number of species is listed. For each of the identified species-rich grassland plots, we provide the following complete information: descriptions of sites, plot characteristics, coordinates, and species lists. Records of one species in different layers (e.g. seedling, juvenile, shrub) are merged into one.

(1) 9 vascular plants species (11 species complete vegetation) / 0.0001 m² (1 cm × 1 cm) (maximum for the steppe zone) – mesic meadow in steppe depression Chorna Dolyna, near Chorna Dolyna village, Kherson Region, coordinates 46.5547N, 33.4796E (recorded using GPS in smartphone), elevation 24 m a.s.l., flat area; land use: pastured in the summer, mown once per year. Plot size measured with a wooden ruler, species recorded as shoot presence, 24.05.2021, authors: Ivan Moysienko, Jürgen Dengler, Iwona Dembicz, Oksana Kucher; nested plot series UAS03NW.

1.	<i>Arenaria serpyllifolia</i> subsp. <i>glutinosa</i>	6.	<i>Scleranthus verticillatus</i>
2.	<i>Cerastium glutinosum</i>	7.	<i>Trifolium retusum</i>
3.	<i>Erophila verna</i>	8.	<i>Ventenata dubia</i>
4.	<i>Lotus angustissimus</i>	9.	<i>Vicia hirsuta</i>
5.	<i>Potentilla argentea</i>		

Bryophytes: *Ptychostomum rubens*, *Tortula truncata*.

(2) 7 vascular plants species (7 species complete vegetation) / 0.0001 m² (1 cm × 1 cm) – bunchgrass steppe, Kamianska ravine near Novokairy village, Kamianska Sich National Nature Park, Kherson Region, coordinates: 47.04559N, 33.58326E (recorded using GPS), elevation 29 m a.s.l., aspect 180°, slope 5°, relief position: middle slope; land use: low-intensity grazing, occasionally burned. Plot size measured with a wooden ruler, species recorded as shoot presence, 07.05.2016, authors: Iwona Dembicz, Lukasz Kozub; nested plot series CHB01NW.

1.	<i>Arenaria serpyllifolia</i>	5.	<i>Kochia prostrata</i>
2.	<i>Bromus squarrosus</i>	6.	<i>Myosotis stricta</i>
3.	<i>Carex supina</i>	7.	<i>Poa bulbosa</i>
4.	<i>Helichrysum arenarium</i>		

(3) 11 vascular plant species (14 species complete vegetation) / 0.001 m² (3 cm × 3 cm) (maximum for the steppe zone) – the same nested plot series as record #1 (UAS03NW).

1.	<i>Anthemis ruthenica</i>	7.	<i>Potentilla argentea</i>
2.	<i>Arenaria serpyllifolia</i> subsp. <i>glutinosa</i>	8.	<i>Scleranthus verticillatus</i>
3.	<i>Cerastium glutinosum</i>	9.	<i>Trifolium retusum</i>
4.	<i>Erophila verna</i>	10.	<i>Ventenata dubia</i>
5.	<i>Lotus angustissimus</i>	11.	<i>Vicia hirsuta</i>
6.	<i>Poa angustifolia</i>		

Bryophytes: *Bryum* sp., *Ptychostomum rubens*, *Tortula truncata*.

(4) 9 vascular plants species (11 species complete vegetation) / 0.001 m² (3 cm × 3 cm) – bunchgrass steppe, Falz-Fein Biosphere Reserve Askania Nova, Kherson Region, coordinates: 46.47478N, 33.913E (recorded using GPS), elevation 24 m a.s.l., flat area; land use: mown once per year. Plot size measured with a wooden ruler, species recorded as shoot presence, 15.05.2017, authors: Iwona Dembicz, Ivan Moysienko, Victor Shapoval; nested plot series CHP08SE.

1.	<i>Arenaria serpyllifolia</i>	6.	<i>Iris pumila</i>
2.	<i>Carex stenophylla</i>	7.	<i>Myosotis stricta</i>
3.	<i>Cruciata pedemontana</i>	8.	<i>Taraxacum erythrospermum</i>
4.	<i>Euphorbia seguieriana</i>	9.	<i>Viola kitaibeliana</i>
5.	<i>Festuca valesiaca</i>		

Bryophytes and lichens: *Cladonia* sp., *Listkowata zielona*.

(5) **9 vascular plants species (9 species complete vegetation) / 0.001 m² (3 cm × 3 cm)** – forb-rich meso-xeric steppe, shadowed slope, near Myhia village, Mykolaiv Region, coordinates: 48.01138N, 30.98688E (recorded using GPS in smartphone), aspect 285°, slope 15°; land use: abandonment. Plot size measured with a wooden ruler, species recorded as shoot presence, 17.06.2021, authors: Dariia Borovyk, Ganna Kolomiets, Jana Ovsienko, Denys Vynokurov; nested plot series SB2105SE.
